Statistical  
Parametric  
Mapping

Nonlinear  
Regression

Parameter  
Identification

Conclusion

- ...
  - Exact variables and parameters are unknown and are difficult to calculate.
  - Significant Amount of Lag between activation and a measurable output
    - can be as much as 8 seconds.
- Slow Temporal Resolution
- Noise characterized by brownian motion
- fft of mri signal, with and without DC

The Bold Response

Statistical  
Parametric  
Mapping

Nonlinear  
Regression

Parameter  
Identification

Conclusion

## ■ Normalized Cerebral Blood Flow:

$$\ddot{f}(t) = \epsilon u(t) - \dot{f}(t)/\tau_s - (f(t)/\tau_f - 1)$$

## ■ Normalized Cerebral Blood Volume:

$$\dot{v}(t) = (1/\tau_0)(f(t) - v(t)^{1/\alpha})$$

## ■ Normalized Deoxyhaemoglobin Content:

$$\dot{q}(t) = \frac{1}{\tau_0} \left( \frac{f(t)(1 - (1 - E_0)^{1/f(t)})}{E_0} - \frac{q(t)}{v(t)^{1-1/\alpha}} \right)$$

## ■ Hemodynamic Response - BOLD Signal

$$y(t) = V_0(a_1(1 - Q(t)) - a_2(1 - V(t)))$$

Identification

Conclusion

- The Balloon Model proposed by [?] is the basic model.
- There are more complicated versions of the BOLD model:
  - [Deneux and Faugeras(2006)] Reviews several existing models
  - [Buxton et al.(2004)Buxton, Uludag, Dubowitz, and Liu] Pioneered the Balloon model which was shown in the beginning.
  - [Zheng et al.(2005)Zheng, Johnston, Berwick, Chen, Billings, and Mayhew] Adds interesting neural activation and a habituation model
  - Some models loosen the link between CMRO<sub>2</sub> (oxygen metabolism) and Cerebral Blood Flow - likely due to several papers that report such a decoupling.
